Cost Attribution Symmetry Index

Quantifying Group Risk without Labeling Belief

Sofience-DeltaPhi Formalism Series
Working Paper / Audit Protocol Framework

Core Declaration

Every benefit stands upon a rearrangement of cost attribution.

The ethical risk of a group does not arise from the unfamiliarity of its belief, but from the asymmetry by which benefits and costs are distributed, delayed, transferred, concealed, or made non-auditable.

A future, sacred, or posthumous compensation claim may console, orient, or reopen meaning; it cannot replace the present duty to attribute, repair, and restabilize costs generated in the present world.

A healthy group is not a perfect group. It is a group that can observe, disclose, repair, and redesign its own cost-attribution failures.

Abstract

SDeltaPhi-58 introduces the Cost Attribution Symmetry Index (CASI), a minimal audit framework for evaluating groups without relying on labels such as orthodox, heterodox, spiritual, ideological, therapeutic, political, or deviant. The document does not judge the truth or falsity of a belief. It measures whether the costs generated under a group's language of truth, salvation, loyalty, progress, healing, sacrifice, discipline, or community are attributed, disclosed, repaired, and re-entered in a symmetric and auditable way.

The central claim is that every benefit stands on a rearrangement of cost attribution. Benefits often announce themselves as growth, efficiency, liberation, blessing, healing, belonging, or mission. Costs, by contrast, are frequently delayed, transferred, externalized, fragmented, spiritualized, or hidden. SDeltaPhi-58 therefore asks not what a group calls sacred, true, beneficial, or necessary, but where the restoration burden of that claim returns.

CASI distinguishes cost-attribution symmetric groups from cost-attribution asymmetric groups. A symmetric group is one in which those who receive benefit also bear proportional cost, affected parties can refuse or exit, failures can be reported safely, authority can be edited, vulnerable members are protected, deferred compensation does not replace present repair, and sacred markers do not block audit. An asymmetric group is one in which benefit flows toward the center while cost is displaced onto members, families, defectors, vulnerable persons, future worlds, silence, or promised compensation beyond present verification.

The paper further introduces evidence grades (CASI-O/R/F/A/E), an Internal Audit Credibility Score (IACS), an Audit Gap Index (AGapI), and an Audit Trust Coefficient (ATC). These distinguish public observation from field investigation, institutional audit, and enforcement. They also allow internal self-assessment and external assessment to be compared without treating disagreement itself as proof of wrongdoing. A large gap is not automatically a negative verdict; it is a reliability signal that requires resolution pathways.

SDeltaPhi-58 therefore turns group evaluation away from stigmatizing labels and toward cost-governance evidence: who benefits, who pays, who can refuse, who can audit, who can repair, and whether recognized failure changes future structure.

Keywords: cost attribution, group risk, audit protocol, sacred marker, deferred compensation, exit cost, internal audit, external audit, SDeltaPhi Formalism, CASI, IACS, audit gap, restoration burden.

1. Problem Statement

Groups that organize belief, loyalty, identity, mission, healing, salvation, discipline, or collective purpose are often evaluated through labels. Such labels may be socially useful, legally relevant, or historically meaningful, but they are also unstable. They can stigmatize unfamiliar groups while missing familiar groups that externalize cost. They can protect established authority while making harm difficult to measure.

SDeltaPhi-58 proposes a lower-level question: not what the group is called, but how the group attributes cost. When a group produces benefit, comfort, belonging, authority, certainty, identity, or status, which parties receive the benefit and which parties bear the restoration burden when harm, error, sacrifice, exploitation, or exit occurs?

This reframing avoids two premature closures. The first closure is hostile labeling: unfamiliar belief is treated as danger by category. The second closure is sacred insulation: familiar or elevated belief is treated as beyond audit. CASI rejects both. It does not measure metaphysical truth. It measures cost-attribution symmetry.

2. Position in the SDeltaPhi Series

SDeltaPhi-58 extends earlier documents into group audit. The sequence can be stated as follows:

- SDeltaPhi-46 distinguished belief, value, and sacred markers, warning that sacred protection can become sacred closure.
- SDeltaPhi-50 converted definitions into questions for future AI, asking where cost returns and what world a system makes cheap.
- SDeltaPhi-51 argued that diagnosis is proven only by re-entry into structural editing.
- SDeltaPhi-54 created a disclosure-terrain index for deciding when silence may count as weak evidence.
- SDeltaPhi-55 created a transition-governance alignment index to avoid both over-obedience and over-refusal.
- SDeltaPhi-56 redefined rollback as restabilization over irreversible trace.
- SDeltaPhi-57 redefined thought-ownership as world-binding, cost attribution, and cost re-entry.

SDeltaPhi-58 applies this cost-attribution sequence to groups. The unit of analysis is not doctrine alone, but the coupled system of belief, authority, money, labor, exit, disclosure, repair, and audit.

3. Minimal Definitions

Term	Definition
Cost attribution	Assignment of restoration burden to an actor, group, member, institution, future party, or external system after a trace has been generated.
Cost attribution symmetry	A condition in which those who receive benefit also bear proportional restoration burden, and affected parties can disclose, refuse, repair, and re-enter cost into structure.
Cost attribution asymmetry	A condition in which benefit is centralized while cost is delayed, transferred, concealed, spiritualized, or externalized to weaker or less visible parties.
Benefit	A reduction of transition friction or expansion of path possibility for a given coordinate. Benefit is observer-indexed and usually announces itself.
Restabilization burden	The weighted friction required to create an acceptable stable state after an irreversible trace has occurred.
Deferred compensation claim	A promise that present loss, sacrifice, or harm will be compensated later, beyond the present verification field.
Sacred marker closure	A condition in which audit, comparison, substitution, exit, or repair becomes framed as violation, betrayal, impurity, disbelief, or desecration.
Internal audit	A group's capacity to observe, record, disclose, investigate, repair, and redesign its own cost-attribution failures.
Audit gap	The measurable difference between internal self-assessment and external assessment of cost-attribution symmetry.

4. Central Propositions

1. Every benefit stands upon a rearrangement of cost attribution.
2. A group's risk is not determined by the strangeness of its belief, but by the asymmetry of its cost design.
3. Deferred compensation cannot cancel present cost attribution.
4. Sacred markers are not false by default, but they become dangerous when they block audit, exit, repair, and re-entry.
5. Internal self-audit and external audit must be reported separately; disagreement is not guilt, but unresolved disagreement lowers reliability.

6. The goal of CASI is not labeling, punishment, or metaphysical judgment. The goal is to make cost-attribution terrain visible.

5. CASI Architecture

CASI uses nine indicators. Each indicator is scored from 0 to 3 and normalized to [0, 1]. Higher is better except DCD and SMC, which are risk axes and are inverted in the final formula.

Code	Indicator	Core question
BCC	Benefit-Cost Coupling	Do those who receive benefit also bear proportional cost?
RSD	Restabilization Duty	When harm, error, or exploitation occurs, does repair duty become real?
ERP	Exit / Refusal Preservation	Can members refuse, dissent, reduce participation, or exit without disproportionate retaliation?
AEV	Audit Evidence Visibility	Can finances, authority, discipline, and harm-handling pathways be inspected?
AED	Authority Editability	Can leadership, interpretation, policy, and decisions be revised?
FTS	Failure-to-Signal Path	Can failure, doubt, injury, abuse, or contradiction be reported safely?
VPR	Vulnerability Protection Ratio	Are vulnerable members protected from cost concentration?
DCD	Deferred Compensation Dependence	Does future or invisible compensation replace present repair?
SMC	Sacred Marker Closure	Does sacred or untouchable language block audit, exit, repair, or critique?

The base structural score is:

$$\text{CASI} = (\text{BCC} * \text{RSD} * \text{ERP} * \text{AEV} * \text{AED} * \text{FTS} * \text{VPR} * (1 - \text{DCD}) * (1 - \text{SMC}))^{(1/9)}$$

A geometric mean is used because severe collapse in one core condition should not be fully compensated by strength elsewhere.

6. Scoring Rubrics

BCC - Benefit-Cost Coupling

Score	Criterion
0	Benefits centralize while costs are routinely displaced to members, families, defectors, vulnerable parties, or future promises.
1	Some cost sharing exists, but leadership or the center is insulated from major restoration burdens.
2	Costs and benefits are partially coupled; leadership and beneficiaries bear some restoration duty.
3	Benefits and costs are visibly coupled; those who benefit also bear proportional repair, transparency, and accountability burdens.

RSD - Restabilization Duty

Score	Criterion
0	Harm, error, or exploitation is denied, spiritualized, blamed on victims, or left unrepaired.
1	Symbolic apology or private handling occurs, but repair is uncertain and recurrence remains likely.
2	Repair pathways exist and sometimes produce compensation, policy change, or recurrence reduction.
3	Repair is documented, externally checkable, and connected to structural changes that reduce recurrence cost.

ERP - Exit / Refusal Preservation

Score	Criterion
0	Exit or refusal triggers threats, shaming, family rupture, economic loss, curse, social death, or surveillance.
1	Formal exit exists but high guilt, stigma, social cost, or informal retaliation remains.
2	Exit and refusal are generally allowed, with some residual social or relational cost.
3	Exit, refusal, reduced participation, and dissent are protected from retaliation and respected as legitimate paths.

AEV - Audit Evidence Visibility

Score	Criterion
0	Finances, discipline, authority, harm handling, and decision records are opaque or inaccessible.
1	Selective disclosure exists, but critical records remain controlled by insiders.
2	Members or reviewers can inspect some meaningful records with limits.
3	Evidence pathways are durable, inspectable, and open to independent review where appropriate.

AED - Authority Editability

Score	Criterion
0	Leadership, revelation, doctrine, interpretation, or disciplinary authority is effectively uneditable.
1	Minor operational edits are possible, but central authority cannot be challenged safely.
2	Authority can be revised through internal procedures, though barriers remain.
3	Authority is bounded, reviewable, corrigible, and separable from personal loyalty to leaders.

FTS - Failure-to-Signal Path

Score	Criterion
0	Reports of harm, doubt, abuse, or failure are punished, ignored, reframed as disloyalty, or suppressed.
1	Reporting is possible but costly, stigmatized, or dependent on trusted insiders.
2	Reporting channels exist and sometimes lead to investigation or repair.
3	Failure signals are protected, logged, investigated, and capable of producing structural editing.

VPR - Vulnerability Protection Ratio

Score	Criterion
0	Children, elderly members, dependent persons, poor members, migrants, patients, or isolated members bear concentrated costs.
1	Vulnerable members are rhetorically valued but lack strong protection or independent recourse.
2	Some protective policies exist and reduce major cost concentration.
3	Vulnerable members receive special protection, independent recourse, and cost-shielding mechanisms.

DCD - Deferred Compensation Dependence

Score	Criterion
0	Future, invisible, or posthumous compensation never replaces present repair or accountability.
1	Deferred compensation language is symbolic and paired with present repair.
2	Deferred compensation is frequently used to reduce pressure for present compensation or reform.
3	Deferred compensation is used to justify sacrifice, silence, poverty,

Score	Criterion
	obedience, or harm without present repair.

SMC - Sacred Marker Closure

Score	Criterion
0	Sacred or core values remain open to harm review, procedural audit, and bounded critique.
1	Some areas are treated with caution, but harm verification and repair remain possible.
2	Critique is often reframed as betrayal, impurity, disbelief, disloyalty, or desecration.
3	Questioning, audit, exit, evidence, or repair is blocked by untouchable sacred authority.

7. Gate Conditions and Interpretive Bands

CASI uses caps and flags so that severe cost-attribution failures cannot be hidden by strong performance elsewhere.

Gate	Condition	Effect
Exit retaliation gate	ERP = 0	CASI capped at 0.35; flag: exit/refusal suppression.
Victim-cost transfer gate	RSD $\leq$ 1 and FTS $\leq$ 1	CASI capped at 0.40; flag: harm non-reentry.
Leader non-audit gate	AEV = 0 and AED $\leq$ 1	CASI capped at 0.40; flag: uneditable center.
Deferred-compensation substitution gate	DCD = 3 and RSD $\leq$ 1	CASI capped at 0.35; flag: future compensation replaces present repair.
Sacred closure gate	SMC = 3 and AEV $\leq$ 1	CASI capped at 0.35; flag: audit blocked by sacred marker.
Vulnerability concentration gate	VPR = 0	CASI capped at 0.30; flag: vulnerable-cost concentration.
Family / property / labor control gate	Strong control without exit protection	CASI capped at 0.25; flag: high externalization risk.
CASI range		Interpretation
0.80-1.00		Cost-attribution symmetric design.
0.60-0.79		Mostly symmetric with visible risk axes.
0.40-0.59		Mixed terrain; structured audit required.
0.20-0.39		Strong cost-attribution asymmetry.
0.00-0.19		High-risk cost externalization terrain.

These bands classify cost-attribution terrain. They do not classify the truth of belief, legality, morality of all members, or final social legitimacy.

8. Evidence Grades: CASI-O/R/F/A/E

A CASI score must always carry an evidence grade. Public observation, repeated coding, field investigation, formal audit, and enforcement do not have the same epistemic weight.

Grade	Name	Minimum evidence	Typical actor
CASI-O	Observed CASI	Public materials: websites, broadcasts, sermons, interviews, public reports, court records, official statements.	Individual researcher, public analyst.
CASI-R	Replicated CASI	Repeated coding of public evidence by multiple reviewers with preserved sources and coding rules.	Independent research team.
CASI-F	Field CASI	Interviews, exit narratives, family reports, internal witnesses, ethnographic or journalistic field evidence.	Journalists, theologians, researchers, civil groups.
CASI-A	Audited CASI	Internal documents, financial records, disciplinary records, harm reports, policy records, independent audit access.	Auditors, institutions, regulators, authorized investigators.

Grade	Name	Minimum evidence	Typical actor
CASI-E	Enforcement CASI	Legal powers, compelled records, protective orders, financial tracing, judicial findings, administrative actions.	Public authority, courts, enforcement agencies.

CASI-O can identify signals. CASI-R improves reproducibility. CASI-F reveals lived cost pathways. CASI-A verifies structure. CASI-E can redistribute cost through enforcement. A lower grade should not be presented as a higher grade.

9. Actor-Specific Use

Actor	Possible grade	Primary role
Individual researcher	CASI-O / partial CASI-R	Detect public risk signals, compare rhetoric and visible cost flows, preserve sources, avoid final accusations.
Independent research team	CASI-R	Replicate scoring, report disagreements, publish coding rules and raw source lists.
Theologian / religious scholar	CASI-O/R/F	Analyze whether sacred, salvation, karma, mission, or obedience language strengthens present repair or delays cost attribution.
Journalist	CASI-F / partial CASI-A	Trace the gap between public language and actual cost flows through testimony and documents.
Civil society group	CASI-F	Protect victims, collect cases, identify patterns, and lower the cost of disclosure.
Internal institutional auditor	CASI-A	Inspect records, finances, discipline, authority, and response pathways.
Public authority	CASI-A/E	Confirm structure through legal powers and execute cost re-attribution when lawful.
Court	CASI-E	Convert verified trace into legal judgment, compensation, protection, or sanction.

10. Internal Audit Credibility Score (IACS)

External audit is not sufficient. A group may be misunderstood from outside, and a group may also misunderstand itself from inside. SDeltaPhi-58 therefore adds a separate index for internal self-audit credibility.

IACS asks whether the group can observe, record, disclose, investigate, repair, and redesign its own cost-attribution failures.

Code	Indicator	Core question
SAD	Self-Audit Disclosure	Can members or relevant outsiders access internal audit results or summaries?
DPP	Dissent Protection	Are internal critics, victims, whistleblowers, and defectors protected from retaliation?
RER	Re-entry Repair	Do internal findings create compensation, policy changes, recurrence reduction, or authority adjustment?
ASI	Audit Separation Independence	Is the auditing body separated from leadership, financial interest, and doctrinal authority?
ETC	Evidence Trace Continuity	Are minutes, financial records, discipline records, harm reports, and repair records durably preserved?
GRC	Gap Response Capacity	When internal and external assessments diverge, is there a process for verification, correction, and public explanation?

$$IACS = (SAD * DPP * RER * ASI * ETC * GRC)^{(1/6)}$$

10.1 IACS Scoring Rubric

Code	Scoring summary
SAD	0: no self-audit disclosed; 1: selective reassurance only; 2: summaries or limited access; 3: meaningful disclosure with evidence pathway.

Code	Scoring summary
DPP	0: dissent punished; 1: dissent tolerated but costly; 2: some protection; 3: dissent and exit protected by rule and practice.
RER	0: no repair; 1: symbolic repair; 2: repair occurs in some cases; 3: repair changes structure and lowers recurrence cost.
ASI	0: auditor controlled by the center; 1: weak separation; 2: partial independence; 3: independent audit with bounded authority.
ETC	0: records absent or erased; 1: fragmented records; 2: durable internal records; 3: durable, reviewable, and protected records.
GRC	0: external criticism dismissed; 1: rebuttal without verification; 2: some comparison process; 3: structured gap resolution with evidence and correction.

11. Audit Gap and Audit Trust

Internal self-assessment and external assessment should be reported separately. Disagreement does not prove wrongdoing. A large unresolved disagreement, however, lowers reliability because no shared cost map exists.

$$\text{AGapI} = \text{abs}(\text{CASI_internal} - \text{CASI_external})$$

AGapI is the Audit Gap Index. It measures the distance between internal and external CASI estimates. It is not a guilt score. It is a reliability signal.

To avoid punishing every disagreement equally, SDeltaPhi-58 uses Gap Resolution:

$$\text{GapResolution} = 1 - (\text{AGapI} * (1 - \text{GRC}))$$

If the gap is large but the group has strong gap-response capacity, trust decreases less severely. If the gap is large and GRC is low, the audit trust collapses.

Audit Trust Coefficient:

$$\text{ATC} = \text{EvidenceGradeWeight} * \text{IACS} * \text{GapResolution}$$

EvidenceGradeWeight may be provisionally set as O = 0.45, R = 0.60, F = 0.75, A = 0.90, E = 1.00. These weights are placeholders for reporting discipline, not final epistemic law.

SDeltaPhi-58 recommends reporting CASI_structural and ATC separately rather than merging them into one moral score.

Condition	Interpretation
High CASI + high IACS + low AGapI	Cost-attribution symmetry and self-audit credibility are both strong.
High CASI + low IACS	Current terrain appears healthy, but self-correction capacity is weak.
Low CASI + high IACS	Cost asymmetry exists, but the group may be capable of repair and redesign.
Low CASI + low IACS	Cost asymmetry and self-audit collapse reinforce one another.
High AGapI + high GRC	Disagreement exists, but verification pathways remain open.
High AGapI + low GRC	Internal and external views diverge without credible resolution; trust is low.

12. Minimal Research Protocol

1. Fix the target scope: specify the group, branch, time period, geography, and evidence grade.
2. Collect public materials: official statements, public teachings, financial appeals, exit statements, public controversies, court or media records.
3. Tag evidence: benefit claim, cost bearer, exit cost, harm report, repair path, deferred compensation, sacred marker, authority boundary, audit pathway.
4. Score each CASI axis with source notes. Do not infer hidden structure beyond evidence grade.

5. If possible, repeat scoring with independent coders and report disagreement.
6. If internal materials or interviews are used, protect vulnerable persons and separate testimony from confirmed records.
7. Calculate CASI, apply gates, assign evidence grade, and report flags.
8. If internal assessment exists, calculate CASI_internal, IACS, AGapI, GapResolution, and ATC.
9. State limits and avoid categorical labeling beyond the evidence grade.
10. Update the score when new evidence, correction, repair, or structural editing occurs.

13. Coding Tags

Tag	Meaning
BEN	Benefit claim: salvation, healing, efficiency, belonging, mission, growth, protection, status, certainty.
CST	Cost bearer: member, family, defector, vulnerable person, staff, future party, outsider.
EXT	Exit/refusal signal: exit allowed, exit punished, exit stigmatized, refusal respected.
AUD	Audit signal: records, accounting, review, independent check, public explanation.
REP	Repair signal: apology, compensation, policy change, reinstatement, protection, recurrence reduction.
DEF	Deferred compensation: later reward, invisible reward, posthumous reward, karmic or cosmic settlement replacing present repair.
SAC	Sacred marker: untouchable authority, forbidden question, critique as betrayal or desecration.
VUL	Vulnerability signal: minors, elderly, poor, isolated, dependent, sick, migrant, subordinate.
GAP	Internal/external disagreement over cost attribution.

14. Abstract Example Patterns

Pattern	SDeltaPhi interpretation
Pattern A: Symmetric community	Members contribute resources and receive support. Leaders publish records. Exit is allowed. Harm reports trigger external review. Future compensation language never replaces present repair. CASI likely high; IACS high if internal audit is credible.
Pattern B: Deferred compensation trap	Members are told that sacrifice will be rewarded beyond present verification. Present poverty, abuse, or labor cost is framed as proof of loyalty. Repair is delayed. DCD high; CASI decreases sharply.
Pattern C: Sacred audit closure	Leadership, doctrine, finances, or discipline cannot be questioned because critique is framed as betrayal or desecration. SMC high; AEV and AED low; gate conditions may cap CASI.
Pattern D: Healthy disagreement	External reviewers score CASI lower than internal auditors, but the group opens records, protects critics, and creates a gap-resolution process. AGapI may be high, but ATC remains moderate or recoverable.
Pattern E: Public virtue, hidden cost	The group publicly emphasizes care and service, but vulnerable members carry unpaid labor, exit cost, or stigma. VPR low, BCC low, FTS weak. CASI flags hidden cost concentration.

15. Relation to Law, Journalism, and Scholarship

CASI is not a substitute for law. It can identify cost-attribution signals before, beside, or after legal judgment, but legal conclusions require jurisdiction-specific evidence, procedure, rights, and standards.

CASI is not a substitute for journalism. It can structure questions, but journalists must verify facts, protect sources, provide right of reply, and avoid turning an index into accusation.

CASI is not a substitute for theology or scholarship. It does not judge ultimate truth. It asks whether truth-claims affect cost attribution, exit, repair, authority, and audit.

CASI is not a tool for suppressing unpopular belief. It is a tool for tracing cost asymmetry. A strange belief with symmetric cost design may be safer than a familiar belief with severe cost externalization.

16. Misuse Limits

- Do not use CASI to label a group by belief category.
- Do not treat CASI-O as CASI-A or CASI-E.
- Do not infer illegality from a low score without legal process.
- Do not turn sacred-marker analysis into contempt for sacred values.
- Do not punish disagreement between internal and external assessments without gap-resolution analysis.
- Do not use the index to force disclosure from vulnerable witnesses.
- Do not reduce complex communities to a single number; report flags, gates, evidence grade, and limits.
- Do not confuse low CASI with the moral status of every member. The index evaluates design terrain, not the soul or worth of persons.

17. Final Formulation

The ethical risk of a group does not lie first in the unfamiliarity of what it believes. It lies in the design of cost attribution under that belief.

A group becomes dangerous when benefit flows inward while cost is pushed outward, delayed into the future, spiritualized beyond verification, concentrated on vulnerable members, or made impossible to audit.

A group becomes healthier when its own failures are observable, its dissenters are protected, its victims are repaired, its authority is editable, its sacred markers do not block harm review, and its internal and external assessments can be reconciled through evidence.

SDeltaPhi-58 therefore asks a lower question than truth and a stricter question than tolerance: when this group produces benefit, where does the cost go, and can that cost return as repair?

Closing Declaration

Every benefit stands upon a rearrangement of cost attribution.

A promise of later compensation cannot cancel the present duty of repair.

A sacred value may protect what should not be cheapened, but it cannot be allowed to make cost invisible.

External criticism alone is not enough. Internal self-audit alone is not enough. A trustworthy group must allow the gap between the two to be measured, disputed, verified, and repaired.

A healthy group is not a group without failure. It is a group in which failure can re-enter as correction and in which the cost of correction does not remain with the harmed alone.

One-Line Summary

SDeltaPhi-58 defines group risk not by belief labeling, but by whether benefits and restoration costs are symmetrically attributed, internally auditable, externally checkable, and capable of re-entering as repair.
